                             include/ansi.h
+++++++++++++++++++++++++++++++++++++++++++++++++++++++++++++++++++++++
00000   /* The <ansi.h> header attempts to decide whether the compiler has enough
00001    * conformance to Standard C for Minix to take advantage of.  If so, the
00002    * symbol _ANSI is defined (as 31459).  Otherwise _ANSI is not defined
00003    * here, but it may be defined by applications that want to bend the rules.
00004    * The magic number in the definition is to inhibit unnecessary bending
00005    * of the rules.  (For consistency with the new '#ifdef _ANSI" tests in
00006    * the headers, _ANSI should really be defined as nothing, but that would
00007    * break many library routines that use "#if _ANSI".)
00008    *
00009    * If _ANSI ends up being defined, a macro
00010    *
00011    *       _PROTOTYPE(function, params)
00012    *
00013    * is defined.  This macro expands in different ways, generating either
00014    * ANSI Standard C prototypes or old-style K&R (Kernighan & Ritchie)
00015    * prototypes, as needed.  Finally, some programs use _CONST, _VOIDSTAR etc
00016    * in such a way that they are portable over both ANSI and K&R compilers.
00017    * The appropriate macros are defined here.
00018    */

                             include/errno.h
++++++++++++++++++++++++++++++++++++++++++++++++++++++++++++++++++++++++++
```

```
00200   /* The <errno.h> header defines the numbers of the various errors that can
00201    * occur during program execution.  They are visible to user programs and
00202    * should be small positive integers.  However, they are also used within
00203    * MINIX, where they must be negative.  For example, the READ system call is
00204    * executed internally by calling do_read().  This function returns either a
00205    * (negative) error number or a (positive) number of bytes actually read.
00206    *
00207    * To solve the problem of having the error numbers be negative inside the
00208    * the system and positive outside, the following mechanism is used.  All the
00209    * definitions are are the form:
00210    *
00211    *      #define EPERM           (_SIGN 1)
00212    *
00213    * If the macro _SYSTEM is defined, then  _SIGN is set to "-", otherwise it is
00214    * set to "".  Thus when compiling the operating system, the  macro _SYSTEM
00215    * will be defined, setting EPERM to (- 1), whereas when when this
00216    * file is included in an ordinary user program, EPERM has the value ( 1).

01300   /* This library provides generic watchdog timer management functionality.
01301    * The functions operate on a timer queue provided by the caller. Note that
01302    * the timers must use absolute time to allow sorting. The library provides:
01303    *
01304    *    tmrs_settimer:     (re)set a new watchdog timer in the timers queue
01305    *    tmrs_clrtimer:     remove a timer from both the timers queue
01306    *    tmrs_exptimers:    check for expired timers and run watchdog functions
01307    *
01308    * Author:
01309    *    Jorrit N. Herder <jnherder@cs.vu.nl>
01310    *    Adapted from tmr_settimer and tmr_clrtimer in src/kernel/clock.c.
01311    *    Last modified: September 30, 2004.

03407    *
03408    * Changes:
03409    *      May 31, 2005: added printf, kputc (relocated from syslib)
03410    *      May 31, 2005: added getuptime
03411    *      Mar 18, 2005: added tickdelay
03412    *      Oct 01, 2004: added env_parse, env_prefix, env_panic
03413    *      Jul 13, 2004: added fkey_ctl
03414    *      Apr 28, 2004: added report, panic
```

```
03415   *        Mar 31, 2004: setup like other libraries, such as syslib
03416   */

++++++++++++++++++++++++++++++++++++++++++++++++++++++++++++++++++++++++++++
                              kernel/table.c
++++++++++++++++++++++++++++++++++++++++++++++++++++++++++++++++++++++++++++

06000   /* The object file of "table.c" contains most kernel data. Variables that
06001    * are declared in the *.h files appear with EXTERN in front of them, as in
06002    *
06003    *     EXTERN int x;
06004    *
06005    * Normally EXTERN is defined as extern, so when they are included in another
06006    * file, no storage is allocated.  If EXTERN were not present, but just say,
06007    *
06008    *     int x;
06009    *
06010    * then including this file in several source files would cause 'x' to be
06011    * declared several times.  While some linkers accept this, others do not,
06012    * so they are declared extern when included normally.  However, it must be
06013    * declared for real somewhere.  That is done here, by redefining EXTERN as
06014    * the null string, so that inclusion of all *.h files in table.c actually
```

```
06015    * generates storage for them.
06016    *
06017    * Various variables could not be declared EXTERN, but are declared PUBLIC
06018    * or PRIVATE. The reason for this is that extern variables cannot have a
06019    * default initialization. If such variables are shared, they must also be
06020    * declared in one of the *.h files without the initialization.  Examples
06021    * include 'boot_image' (this file) and 'idt' and 'gdt' (protect.c).
06022    *
06023    * Changes:
06024    *    Aug 02, 2005   set privileges and minimal boot image (Jorrit N. Herder)
06025    *    Oct 17, 2004   updated above and tasktab comments  (Jorrit N. Herder)
06026    *    May 01, 2004   changed struct for system image  (Jorrit N. Herder)

       ++++++++++++++++++++++++++++++++++++++++++++++++++++++++++++++++++++++++++
                              kernel/mpx386.s
       ++++++++++++++++++++++++++++++++++++++++++++++++++++++++++++++++++++++++++

06300  #
06301  ! This file, mpx386.s, is included by mpx.s when Minix is compiled for
06302  ! 32-bit Intel CPUs. The alternative mpx88.s is compiled for 16-bit CPUs.
06303
06304  ! This file is part of the lowest layer of the MINIX kernel.  (The other part
06305  ! is "proc.c".)  The lowest layer does process switching and message handling.
06306  ! Furthermore it contains the assembler startup code for Minix and the 32-bit
06307  ! interrupt handlers.  It cooperates with the code in "start.c" to set up a
06308  ! good environment for main().
06309
06310  ! Every transition to the kernel goes through this file.  Transitions to the
06311  ! kernel may be nested.  The initial entry may be with a system call (i.e.,
06312  ! send or receive a message), an exception or a hardware interrupt;  kernel
06313  ! reentries may only be made by hardware interrupts.  The count of reentries
06314  ! is kept in "k_reenter". It is important for deciding whether to switch to
06315  ! the kernel stack and for protecting the message passing code in "proc.c".
06316
06317  ! For the message passing trap, most of the machine state is saved in the
06318  ! proc table.  (Some of the registers need not be saved.)  Then the stack is
06319  ! switched to "k_stack", and interrupts are reenabled.  Finally, the system
06320  ! call handler (in C) is called.  When it returns, interrupts are disabled
06321  ! again and the code falls into the restart routine, to finish off held-up
06322  ! interrupts and run the process or task whose pointer is in "proc_ptr".
06323
06324  ! Hardware interrupt handlers do the same, except  (1) The entire state must
06325  ! be saved.  (2) There are too many handlers to do this inline, so the save
06326  ! routine is called.  A few cycles are saved by pushing the address of the
06327  ! appropiate restart routine for a return later.  (3) A stack switch is
06328  ! avoided when the stack is already switched.  (4) The (master) 8259 interrupt
06329  ! controller is reenabled centrally in save().  (5) Each interrupt handler
06330  ! masks its interrupt line using the 8259 before enabling (other unmasked)
06331  ! interrupts, and unmasks it after servicing the interrupt.  This limits the
06332  ! nest level to the number of lines and protects the handler from itself.
06333
06334  ! For communication with the boot monitor at startup time some constant
06335  ! data are compiled into the beginning of the text segment. This facilitates
06336  ! reading the data at the start of the boot process, since only the first
06337  ! sector of the file needs to be read.
06338
06339  ! Some data storage is also allocated at the end of this file. This data
06340  ! will be at the start of the data segment of the kernel and will be read
06341  ! and modified by the boot monitor before the kernel starts.

+++++++++++++++++++++++++++++++++++++++++++++++++++++++++++++++++++++++++++
                        kernel/proc.c
+++++++++++++++++++++++++++++++++++++++++++++++++++++++++++++++++++++++++++

07400  /* This file contains essentially all of the process and message handling.
07401   * Together with "mpx.s" it forms the lowest layer of the MINIX kernel.
07402   * There is one entry point from the outside:
07403   *
07404   *   sys_call:      a system call, i.e., the kernel is trapped with an INT
07405   *
07406   * As well as several entry points used from the interrupt and task level:
07407   *
07408   *   lock_notify:   notify a process of a system event
07409   *   lock_send:     send a message to a process
07410   *   lock_enqueue:  put a process on one of the scheduling queues
07411   *   lock_dequeue:  remove a process from the scheduling queues
07412   *
07413   * Changes:
07414   *   Aug 19, 2005   rewrote scheduling code  (Jorrit N. Herder)
07415   *   Jul 25, 2005   rewrote system call handling  (Jorrit N. Herder)
07416   *   May 26, 2005   rewrote message passing functions  (Jorrit N. Herder)
07417   *   May 24, 2005   new notification system call  (Jorrit N. Herder)
07418   *   Oct 28, 2004   nonblocking send and receive calls  (Jorrit N. Herder)
07419   *
```

```
07420   * The code here is critical to make everything work and is important for the
07421   * overall performance of the system. A large fraction of the code deals with
07422   * list manipulation. To make this both easy to understand and fast to execute
07423   * pointer pointers are used throughout the code. Pointer pointers prevent
07424   * exceptions for the head or tail of a linked list.
07425   *
07426   *  node_t *queue, *new_node;   // assume these as global variables
07427   *  node_t **xpp = &queue;      // get pointer pointer to head of queue
07428   *  while (*xpp != NULL)        // find last pointer of the linked list
07429   *      xpp = &(*xpp)->next;    // get pointer to next pointer
07430   *  *xpp = new_node;            // now replace the end (the NULL pointer)
07431   *  new_node->next = NULL;      // and mark the new end of the list
07432   *
07433   * For example, when adding a new node to the end of the list, one normally
07434   * makes an exception for an empty list and looks up the end of the list for
07435   * nonempty lists. As shown above, this is not required with pointer pointers.

        ++++++++++++++++++++++++++++++++++++++++++++++++++++++++++++++++++++++++++

 09700   /* This task provides an interface between the kernel and user-space system
 09701    * processes. System services can be accessed by doing a kernel call. Kernel
 09702    * calls are  transformed into request messages, which are handled by this
 09703    * task. By convention, a sys_call() is transformed in a SYS_CALL request
 09704    * message that is handled in a function named do_call().
 09705    *
 09706    * A private call vector is used to map all kernel calls to the functions that
 09707    * handle them. The actual handler functions are contained in separate files
 09708    * to keep this file clean. The call vector is used in the system task's main
 09709    * loop to handle all incoming requests.
 09710    *
 09711    * In addition to the main sys_task() entry point, which starts the main loop,
 09712    * there are several other minor entry points:
 09713    *   get_priv:         assign privilege structure to user or system process
 09714    *   send_sig:         send a signal directly to a system process
 09715    *   cause_sig:        take action to cause a signal to occur via PM
 09716    *   umap_local:       map virtual address in LOCAL_SEG to physical
 09717    *   umap_remote:      map virtual address in REMOTE_SEG to physical
 09718    *   umap_bios:        map virtual address in BIOS_SEG to physical
 09719    *   virtual_copy:     copy bytes from one virtual address to another
 09720    *   get_randomness:   accumulate randomness in a buffer
 09721    *
 09722    * Changes:
 09723    *   Aug 04, 2005   check if kernel call is allowed  (Jorrit N. Herder)
 09724    *   Jul 20, 2005   send signal to services with message  (Jorrit N. Herder)
```

```
09725  *    Jan 15, 2005   new, generalized virtual copy function  (Jorrit N. Herder)
09726  *    Oct 10, 2004   dispatch system calls from call vector  (Jorrit N. Herder)
09727  *    Sep 30, 2004   source code documentation updated  (Jorrit N. Herder)

++++++++++++++++++++++++++++++++++++++++++++++++++++++++++++++++++++++++++

10400  /* This file contains the clock task, which handles time related functions.
10401   * Important events that are handled by the CLOCK include setting and
10402   * monitoring alarm timers and deciding when to (re)schedule processes.
10403   * The CLOCK offers a direct interface to kernel processes. System services
10404   * can access its services through system calls, such as sys_setalarm(). The
10405   * CLOCK task thus is hidden from the outside world.
10406   *
10407   * Changes:
10408   *   Oct 08, 2005   reordering and comment editing (A. S. Woodhull)
10409   *   Mar 18, 2004   clock interface moved to SYSTEM task (Jorrit N. Herder)
10410   *   Sep 30, 2004   source code documentation updated  (Jorrit N. Herder)
10411   *   Sep 24, 2004   redesigned alarm timers  (Jorrit N. Herder)
10412   *
10413   * The function do_clocktick() is triggered by the clock's interrupt
10414   * handler when a watchdog timer has expired or a process must be scheduled.
10415   *
10416   * In addition to the main clock_task() entry point, which starts the main
10417   * loop, there are several other minor entry points:
10418   *   clock_stop:      called just before MINIX shutdown
10419   *   get_uptime:      get realtime since boot in clock ticks
10420   *   set_timer:       set a watchdog timer (+)
10421   *   reset_timer:     reset a watchdog timer (+)
10422   *   read_clock:      read the counter of channel 0 of the 8253A timer
10423   *
10424   * (+) The CLOCK task keeps tracks of watchdog timers for the entire kernel.
10425   * The watchdog functions of expired timers are executed in do_clocktick().
10426   * It is crucial that watchdog functions not block, or the CLOCK task may
10427   * be blocked. Do not send() a message when the receiver is not expecting it.
10428   * Instead, notify(), which always returns, should be used.

++++++++++++++++++++++++++++++++++++++++++++++++++++++++++++++++++++++++++++
                             drivers/tty/tty.c
++++++++++++++++++++++++++++++++++++++++++++++++++++++++++++++++++++++++++++

13600   /* This file contains the terminal driver, both for the IBM console and regular
13601    * ASCII terminals.  It handles only the device-independent part of a TTY, the
13602    * device dependent parts are in console.c, rs232.c, etc.  This file contains
13603    * two main entry points, tty_task() and tty_wakeup(), and several minor entry
13604    * points for use by the device-dependent code.
13605    *
13606    * The device-independent part accepts "keyboard" input from the device-
13607    * dependent part, performs input processing (special key interpretation),
13608    * and sends the input to a process reading from the TTY.  Output to a TTY
13609    * is sent to the device-dependent code for output processing and "screen"
13610    * display.  Input processing is done by the device by calling 'in_process'
13611    * on the input characters, output processing may be done by the device itself
13612    * or by calling 'out_process'.  The TTY takes care of input queuing, the
13613    * device does the output queuing.  If a device receives an external signal,
13614    * like an interrupt, then it causes tty_wakeup() to be run by the CLOCK task
13615    * to, you guessed it, wake up the TTY to check if input or output can
13616    * continue.
13617    *
13618    * The valid messages and their parameters are:
13619    *
13620    *    HARD_INT:       output has been completed or input has arrived
13621    *    SYS_SIG:        e.g., MINIX wants to shutdown; run code to cleanly stop
13622    *    DEV_READ:       a process wants to read from a terminal
13623    *    DEV_WRITE:      a process wants to write on a terminal
13624    *    DEV_IOCTL:      a process wants to change a terminal's parameters
13625    *    DEV_OPEN:       a tty line has been opened
13626    *    DEV_CLOSE:      a tty line has been closed
13627    *    DEV_SELECT:     start select notification request
13628    *    DEV_STATUS:     FS wants to know status for SELECT or REVIVE
13629    *    CANCEL:         terminate a previous incomplete system call immediately
```

                         drivers/tty/console.c
++++++++++++++++++++++++++++++++++++++++++++++++++++++++++++++++++++++++++

 15900  /* Code and data for the IBM console driver.
 15901   *
 15902   * The 6845 video controller used by the IBM PC shares its video memory with
 15903   * the CPU somewhere in the 0xB0000 memory bank.  To the 6845 this memory
 15904   * consists of 16-bit words.  Each word has a character code in the low byte
 15905   * and a so-called attribute byte in the high byte.  The CPU directly modifies
 15906   * video memory to display characters, and sets two registers on the 6845 that
 15907   * specify the video origin and the cursor position.  The video origin is the
 15908   * place in video memory where the first character (upper left corner) can
 15909   * be found.  Moving the origin is a fast way to scroll the screen.  Some
 15910   * video adapters wrap around the top of video memory, so the origin can
 15911   * move without bounds.  For other adapters screen memory must sometimes be
 15912   * moved to reset the origin.  All computations on video memory use character
 15913   * (word) addresses for simplicity and assume there is no wrapping.  The
 15914   * assembly support functions translate the word addresses to byte addresses
 15915   * and the scrolling function worries about wrapping.

++++++++++++++++++++++++++++++++++++++++++++++++++++++++++++++++++++++++++++

22100   /* Super block table.  The root file system and every mounted file system
22101    * has an entry here.  The entry holds information about the sizes of the bit
22102    * maps and inodes.  The s_ninodes field gives the number of inodes available
22103    * for files and directories, including the root directory.  Inode 0 is
22104    * on the disk, but not used.  Thus s_ninodes = 4 means that 5 bits will be
22105    * used in the bit map, bit 0, which is always 1 and not used, and bits 1-4
22106    * for files and directories.  The disk layout is:
22107    *
22108    *    Item         # blocks
22109    *    boot block     1
22110    *    super block    1     (offset 1kB)
22111    *    inode map    s_imap_blocks
22112    *    zone map     s_zmap_blocks
22113    *    inodes       (s_ninodes + 'inodes per block' - 1)/'inodes per block'
22114    *    unused       whatever is needed to fill out the current zone
22115    *    data zones   (s_zones - s_firstdatazone) << s_log_zone_size
22116    *
22117    * A super_block slot is free if s_dev == NO_DEV.
